Abstract

We have recently shown that BCG (Bacillus Calmette-Guérin) vaccination in healthy volunteers induces epigenetic reprogramming of monocytes, leading to increased cytokine production in response to nonrelated pathogens for up to 3 months after vaccination. This phenomenon was named 'trained immunity'. In the present study we assessed whether BCG was able to induce long-lasting effects on both trained immunity and heterologous T helper 1 (Th1) and Th17 immune responses 1 year after vaccination. The production of TNF α and IL-1 β to mycobacteria or unrelated pathogens was higher after 2 weeks and 3 months postvaccination, but these effects were less pronounced 1 year after vaccination. However, monocytes recovered 1 year after vaccination had an increased expression of pattern recogni-

tion receptors such as CD14, Toll-like receptor 4 (TLR4) and mannose receptor, and this correlated with an increase in proinflammatory cytokine production after stimulation with the TLR4 ligand lipopolysaccharide. The heterologous production of Th1 (IFN- γ) and Th17 (IL-17 and IL-22) immune responses to nonmycobacterial stimulation remained strongly elevated even 1 year after BCG vaccination. In conclusion, BCG induces sustained changes in the immune system associated with a nonspecific response to infections both at the level of innate trained immunity and at the level of heterologous Th1/Th17 responses.

Introduction

Nonspecific beneficial effects of BCG (Bacillus Calmette-Guérin) have been described for many decades. Soon after its introduction in the 1920s, epidemiological

studies surprisingly demonstrated that BCG protects against infant mortality independent of its effect on tuberculosis (TB) [1–5]. Recent studies supported these findings and suggested a reduction of the burden of infections other than TB [6–10]. For example, BCG decreased by half the neonatal mortality of children in several recent trials in West Africa [8, 9, 11–14], while in a case-control study in Brazil, BCG reduced the risk of death from pneumonia by 50% in children less than 1 year of age [7]. In light of these data, the question arises as to which mechanisms mediate these nonspecific immune effects of BCG, and how long do they last?

Two possible immunological mechanisms have been proposed to explain the nonspecific beneficial effects of vaccination. The first such mechanism is heterologous immunity, in which cross-protection is mediated by heterologous T cell memory responses [15]. However, heterologous immunity needs at least a couple of weeks to develop, and it is thus highly unlikely to be responsible for the very rapid effects observed on perinatal immunity [14]. A second mechanism of protection has been recently proposed in the form of epigenetic reprogramming of immune cells, a phenomenon conferring nonspecific immune memory to innate immune responses and termed ‘trained immunity’ [16]. Many species of organisms lacking adaptive immunity, such as plants [17] or insects [18, 19], manifest robust immune memory after previous exposure to infections or certain microbial components, and adaptive features of innate immunity have also been demonstrated in mice devoid of functional adaptive immune responses [20, 21]. Prominent microbial components that are able to potentiate the effector function of innate immune cells and protect against infections are mycobacterial stimuli such as BCG, complete Freund’s adjuvant and muramyl dipeptide [22–25]. Recently, we have shown that BCG vaccination in healthy volunteers led to NOD2-dependent epigenetic reprogramming of monocytes, which resulted in an increased expression of cellular receptors on the monocytes, accompanied by higher cytokine production in response to nonrelated pathogens [26]. This newly described mechanism might represent the explanation for the rapid nonspecific protective effects induced by BCG vaccination. However, it is not known how long trained immunity and/or heterologous immunity persist after BCG vaccination. Therefore, in the present study we investigated the long-term nonspecific effects of BCG vaccination in healthy volunteers by assessing the responses of both innate and adaptive immune cells to nonmycobacterial stimulation in a period extending up until 1 year after the vaccination.

Materials and Methods

Subjects

Individuals (age range 20–36 years) scheduled to receive a BCG vaccination at the public health service because of travel to or work in TB-endemic countries were asked to participate in this trial. Twenty healthy individuals were included between August and November 2010. Blood was drawn before, and 2 weeks, 3 months and 1 year after the BCG vaccination. Two participants were lost to follow-up after 3 months. The study was approved by the Arnhem-Nijmegen Ethical Committee.

PBMC Stimulation Assays

For the PBMC stimulation assays the mononuclear cell fraction was isolated by density centrifugation from blood diluted 1:1 in pyrogen-free saline over Ficoll-Paque (Pharmacia Biotech, Uppsala, Sweden). Cells were washed twice in saline and resuspended in culture medium (RPMI, Invitrogen, Carlsbad, Calif., USA) supplemented with gentamicin 10 µg/ml, L-glutamine 10 mM and pyruvate 10 mM. Cells were counted in a Coulter counter (Coulter Electronics) and the number was adjusted to 5×10^6 cells/ml. A total of 5×10^5 mononuclear cells in a 100-µl volume was added to round-bottomed 96-well plates (Greiner) with RPMI or with sonicated *Mycobacterium tuberculosis* (MTB) H37Rv (1 µg/ml end protein concentration), heat-killed *Candida albicans* (1×10^6 microorganisms/ml, strain UC820), *Staphylococcus aureus* (1×10^6 microorganisms/ml, clinical isolate) or *Escherichia coli* lipopolysaccharide (LPS; 1 ng/ml; Sigma-Aldrich, St. Louis, Mo., USA). After 24, 48 h or 7 days supernatants were stored at -20°C . Cytokine concentrations were assessed in the supernatants using enzyme-linked immunosorbent assay (ELISA).

Cytokine Measurements

Circulating IFN- γ , IL-17 and IL-22 were measured in plasma with Sanquin Pelikine ELISA kits (IFN- γ) or R&D Quantikine ELISA kits (IL-17 and IL-22; R&D Systems, Minneapolis, Minn., USA), respectively, following the description of the manufacturer. Cytokine measurements of TNF α , IL-1 β , IFN- γ , IL-17 and IL-22 after PBMC stimulation were performed in the supernatants using commercial ELISA kits from R&D Systems (TNF α , IL-1 β , IL-17 and IL-22) or Sanquin (IFN- γ ; Amsterdam, The Netherlands). In a small proportion of baseline samples in which cytokine concentrations were beyond the detection limit, these outliers were excluded from the analysis.

FACS Analysis

Cells were phenotypically analyzed by ten-color and five-color flow cytometry using a Coulter Navios and Coulter Cytomics FC 500, respectively (Beckman Coulter, Fullerton, Fla., USA) and evaluated using Kaluza 1.1 software (Beckman Coulter). In order to guarantee reliable results the flow cytometry was calibrated with flow set pro beads (Beckman Coulter). Cells were washed in PBS with 1% bovine serum albumin before being labeled with fluorochrome-conjugated mAbs. After incubation for 30 min at 4°C in the dark, cells were washed twice to remove unbound antibodies and analyzed. For cell surface staining, the following mAbs were used: CD3-PECy7 (737657), CD4-PB (A82789), CD8-APC-A700 (A66332), CD45-PO (A96416), CD11b-PE (IM25814), CD14-ECD (IM2707U), CD45-PC7 (IM3548; all from Beckman Coulter Corporation), CD284-PE (TLR4; 312806) and CD206-PE (321106;

Fig. 1. BCG vaccination increased the heterologous Th1 responses. PBMCs isolated from 18 volunteers before and after (2 weeks, 3 months and 1 year) vaccination were stimulated in vitro with

sonicated *MTB* (a), heat-killed *C. albicans* yeast (b) and *S. aureus* (c). IFN- γ production was assessed in the supernatants by ELISA. * $p < 0.05$; ** $p < 0.01$.

both form Biolegend), CD16-FITC (335035) and CD282-APC (TLR2; 558319; both from BD biosciences) and dectin-1-APC (FAB1859A; R&D Systems).

Statistical Analysis

Differences were analyzed using the Wilcoxon signed-rank test or Friedman test for paired samples. $p < 0.05$ was considered statistically significant. Unless otherwise stated, data are shown as cumulative results of data obtained in all volunteers (means + SEM).

Results

The Effect of BCG Vaccination on Heterologous Th1 and Th17 Responses

FACS analyses of T cell subpopulations did not show major shifts in CD4 and CD8 lymphocytes (online suppl. fig. 1; for all online suppl. material, see www.karger.com/doi/10.1159/000355628). Circulating concentrations of the T cell-derived cytokines IFN- γ , IL-17 and IL-22 were below the detection limit at all time points (data not shown). In contrast, 2 weeks and 3 months after BCG vaccination, IFN- γ production induced by *MTB* was 7-fold higher than the production before vaccination, as also reported previously [26]. Interestingly, this effect remained present for at least 1 year (fig. 1a). A similar increase in cytokine production after 2 weeks and 3 months was observed when cells were stimulated with unrelated pathogens (*C. albicans* or *S. aureus*; fig. 1b, c). The increased production persisted until 1 year after vaccination in the case of *S. aureus*, while it largely returned to prevaccination levels after *C. albicans* stimulation.

In addition to its effects on Th1 responses, we sought to investigate the effect of BCG vaccination on the production of Th17-derived cytokines, namely IL-17 and IL-22. *MTB*-stimulated IL-17 production was significantly

higher in cells retrieved after BCG vaccination (fig. 2a). Moreover, this effect was independent of the stimulating pathogen, as a persistently increased IL-17 production was also observed upon stimulation with *C. albicans* (fig. 2b) and *S. aureus* (fig. 2c). The increased heterologous Th17 immunity was also reflected by the potentiated IL-22 production after BCG vaccination. This was apparent after stimulation of cells with *MTB*, *C. albicans* or *S. aureus* (fig. 2d–f).

The Effect of BCG Vaccination on Trained Immunity

Previously, we reported that BCG affected production of proinflammatory cytokines produced by monocytes, a prototypic innate immune cell population [26]. While TNF α and IL-1 β production was higher 2 weeks and 3 months after vaccination, it largely returned to normal 1 year after BCG vaccination. This waning effect on TNF α and IL-1 β release was observed upon stimulation of the cells with *MTB*, as well as with the nonrelated pathogen *C. albicans* (fig. 3a, b) or *S. aureus* (not shown). Similar data were obtained on IL-1 β production (data not shown). However, LPS-induced TNF α (fig. 3c) and IL-1 β (fig. 3d) production 1 year after vaccination remained significantly higher compared to prevaccination levels.

The Effect of BCG Vaccination on Receptor Expression on Monocytes

The expression of several pattern recognition receptors and activation markers on monocytes showed a sustained rise in expression over time. Figure 4 presents mean fluorescent indexes (MFI) of either markers of activity of monocytes (CD14 and CD11b; fig. 4a, b), Toll-like receptor 4 (TLR4) and TLR2 (fig. 4c, d), and C-type lectins (mannose receptor, MR, and dectin-1; fig. 4e, f). The increase in MFI was receptor specific, as not all TLRs

or C-type lectins were influenced by the vaccination. The activity markers CD14 and CD11b showed persistent higher levels of expression on monocytes that lasted for at least 1 year. Also, TLR4 and MR expression on monocytes were increased after BCG vaccination 1 year after vaccina-

tion. No effect was seen on the expression of TLR2 or decin-1 (fig. 4d, f). Online supplementary figure 2 shows the gating strategy for monocytes used in figure 4. In addition, online supplementary figure 3 presents representative histograms of all the receptors shown in figure 4.

C-type lectin receptors MR (e) and dectin-1 (f) within the CD14+ monocytes population isolated from 18 volunteers before and after BCG vaccination. * $p < 0.05$; ** $p < 0.01$; *** $p < 0.005$.

Discussion

BCG has beneficial effects on infections other than TB, yet the immunological mechanisms responsible for these effects remain obscure. Recently, two immunological mechanisms have been suggested to mediate these effects: the short-time effects are most likely mediated by epigenetic reprogramming of innate immune cells, a process called ‘trained immunity’ [26], while long-term effects may be mediated by heterologous Th1/Th17 immunity [15], possibly in combination with residual trained immunity effects. In the present study we show that BCG vaccination induces nonspecific potentiation effects of both innate trained immunity and heterologous T helper responses that are clearly present for at least 1 year after vaccination.

The long-term effects after BCG vaccination are most prominent on heterologous Th1 and Th17 responses. An explanation for this could be the process of ‘cross-protection’ described 5 decades ago [27], or termed later as ‘heterologous immunity’ [15, 28]. The classical form of cross-protection is mediated by lymphocytes that release IFN- γ after stimulation with a first-encountered pathogen and subsequently activate bystander macrophages, generating a state of temporary heightened innate immunity against a secondary infection, which wanes rapidly once the primary pathogen is eliminated [29]. The second

form is long-lived and therefore maybe more comparable with our findings: Berg et al. [30] described that both effector and memory CD8+ cells have the potential to secrete IFN- γ in response to IL-12 and IL-18 in the absence of a related antigen. The IL-12 and IL-18 are produced in the initial stages of a secondary infection. One additional possible explanation can be epitope sharing as described previously, although this is unlikely to play a major role for explaining the increased responses to *C. albicans* or *S. aureus* after BCG vaccination.

One could speculate that the increased reactivity of Th17 cells occurs in a similar fashion. The general principle of the induction of Th17 responses is similar to that of Th1 immunity, with the difference that IL-1 β and IL-23 (rather than IL-12 and IL-18) are the cytokines responsible for Th17 differentiation. The increased expression of pattern recognition receptors known to induce Th17 responses such as MR [31], and proinflammatory cytokines such as IL-1 β [32], may at least partly account for the induction of heterologous Th17 immunity. The increase in these typical innate immune responses during the induction of trained immunity could thus contribute to heterologous T helper responses, but this direct relationship remains to be formally demonstrated by future studies. In addition, one may also speculate regarding potential deleterious effects of BCG-induced heterologous

immunity during autoimmune processes. An important difference between BCG vaccination and autoimmune disorders is that while autoimmunity induces spontaneous IL-17 production with autoimmune tissue damage, BCG vaccination only induces a primed status of the cells to respond more strongly to secondary microbial stimulation. Without stimulation, no higher production of these cytokines was seen. In line with this, one study even reported a beneficial effect of BCG vaccination on type 1 diabetes mellitus [33], and beneficial effects on asthma and allergies have also been reported [34].

In addition to the effects on heterologous immunity, BCG vaccination also shows long-term effects on innate trained immunity. This is revealed by the persistent increase in LPS-mediated proinflammatory cytokine production, and expression of pattern recognition receptors and monocyte activation markers. One may hypothesize that these two effects are related, as it is mainly the expression of the LPS receptors TLR4 and CD14 [35], which remained high 1 year after BCG, that are responsible for enhanced cytokine responses after LPS stimulation. In contrast, the expression of other pattern recognition receptors such as dectin-1 and TLR2 was not affected by BCG vaccination. While alterations in *S. aureus* and *C. albicans*-mediated cytokine production were clearly present 2 weeks and 3 months after vaccination, these effects waned after 1 year. This suggests that at least for some innate immune pathways, the epigenetic reprogramming responsible for the trained immunity effects [26] are relatively short lived and are present for months rather than years.

In conclusion, in the present study we have characterized the long-term nonspecific immunological effects of BCG vaccination. We have previously shown that innate immunity has adaptive features, termed trained immunity [16]. While a maximum duration of trained immunity effects of 3 months has been reported to date [26], in the present study we have shown that the nonspecific training effects of BCG vaccination on receptor expression and LPS-induced proinflammatory cytokines is long-standing and present for at least 1 year. In addition, strongly increased heterologous Th1 and Th17 responses have been observed 1 year after the vaccination. These double effects of BCG vaccination on both trained immunity and heterologous T cell responses provide a likely explanation for both the short- and long-term nonspecific effects of BCG, which have been known for decades and may have important implications for vaccine development and healthcare policy.
